```

Find recommended sample size for this study

```
# calculate min sample size needed
pop_size <- nrow(heartattack) # 3139

# using 95% CI, find n for worst case scenario: p = 0.5
MOE <- 0.05
z <- 1.96
p_guess <- 0.5

# if N is large enough to ignore FPC
n_0 = ceiling( ((2*z)^2*(0.5)*(0.5)) / (MOE^2)) # 1537
# since we know N = 8763, using FPC
n = ceiling( n_0 / (1 + (n_0/pop_size)) ) # 1032
```

Assuming the worst case proportions 0.5, the sample size used if we ignored FPC is 1537. Whereas including FPC the sample size used in SRS will be 1032.

Compare study design for stratification

```
#Calculate within variance of each sex: Male, Female
variance_within_strata <- aggregate(BMI ~ Sex, heartattack, var)
colnames(variance_within_strata) <- c("Sex","Within Variance Sex")
print(variance_within_strata)
```

Method 1: stratify by sex

```
##      Sex Within Variance Sex
## 1 Female            38.33507
## 2   Male            40.77213
```

```

##   Overall Obesity Var.
## 1             40.06844
```

By computing and comparing the within variances based on different stratas, stratifying by sex gave the lowest overall within variance of 39.09994. Since the stratification study design performs the best for the largest between-strata variance, implying the lowest within-strata variance, we will stratify by sex.

In the two stratums: Sex =: (Male, Female), sample size for Male is 2195 and sample size for Female is 944

Selecting Samples through SRS and Stratification by sex

```
# set seed
set.seed(2023)

# take SRS of n = 1308
SRS.index <- sample.int(pop_size, n, replace=F)
SRS_sample <- heartattack[SRS.index, ]
head(SRS_sample)
```

```
